ABSTRACT. We present in this paper a high order discontinuous Galerkin method for the elastodynamic equations in the time domain. Our approach combines an arbitrary order spatial interpolation, centered fluxes and a high order leapfrog scheme for the time integration. Numerical results for the propagation of a 2D eigenmode are presented for second and fourth-order leapfrog schemes. We also propose a numerical study of the stability and the convergence of the method proving the accuracy of the scheme for both regular and irregular meshes.

KEYWORDS : elastodynamic equation, discontinuous Galerkin method, leapfrog scheme, centered scheme
1. INTRODUCTION

Computational seismology has become a very important discipline for the study of seismic wave propagation, as analytical solutions only exist in few simple cases like homogeneous domains or simple geometries. Various numerical methods have been developed to solve such problems. Among them, we can mention the finite difference method [14][10], the classical finite element method [9][11], the spectral and pseudospectral methods [8], and the finite volume method [3]. We choose to use a high-order Discontinuous Galerkin (DG) method applied to triangular meshes. The DG method has been initially introduced by Reed and Hill for the solution of the neutron transport equation. Neglected during many years, it is now very popular to solve hyperbolic problems. In spite of its success in many domains of applications, this method has been rarely applied to seismic wave propagation problems [12]. Käser et al. ([7] and many references therein) proposed a DG finite element scheme based on upwind fluxes and the ADER approach in order to solve the elastodynamic system with the same high accuracy in space and time. Antonietti et al. [2] compared the Mortar spectral element method and the DG spectral element method, both on non-conforming rectangular meshes, with a second order leapfrog scheme for the time integration. They found that those two methods have a good accuracy while used for the simulation of the elastodynamic equations. Agut et al [1] developed a new high order method based on the "Modified Equation" technique in time, coupled with a DG method in space for the discretisation of the additional biharmonic operator, for the solution of the acoustic wave equation. Their results show that the computational cost of their scheme is the same as the one of the leapfrog scheme.

In this paper, we study the P-SV wave propagation in an isotropic, linear elastic medium by solving the velocity-stress formulation of the elastodynamic equations. Our method is based on centered fluxes and a leapfrog time-discretization which leads to a non-dissipative scheme [4]. These are the differences between our approach and the one developed by Käser et al. ([7]). According to the first results of the method presented in [4], the time accuracy of the scheme is crucial when global high-accuracy is required. Then, we propose an extension of the leapfrog scheme to higher orders of accuracy, following a method proposed for the Maxwell equations by Young [15] or Spachmann et al. [13] and applied to DG methods by Fahs [5]. This method allows us to achieve temporal accuracy to any even order desired by introducing an iterative procedure. We restrict here ourselves to the fourth-order leap-frog scheme since we consider a spatial interpolation based on fourth-degree polynomial functions at most. The method is applied to the propagation of an eigenmode in the unit square cavity. The numerical study of the stability and the convergence of the method is also studied for both regular and irregular meshes.

2. EQUATIONS AND SPATIAL DISCRETIZATION

In a linear, isotropic and infinite medium, the P-SV wave propagation is modelled by the elastodynamic equation which can be written in velocity-stress formulation [14]

\[
\begin{align*}
\rho \partial_t \vec{v} &= \nabla \cdot \sigma, \\
\partial_t \sigma &= \lambda(\nabla \cdot \vec{v})I + \mu(\nabla \vec{v} + (\nabla \vec{v})^t),
\end{align*}
\]

where \(\vec{v}\) is the velocity vector, \(\sigma\) the stress tensor, \(\rho\) the density of the medium, \(I\) is the identity matrix and \(\lambda\) and \(\mu\) the Lamé coefficients describing the rheology of the medium, related to the P- and S-wave velocities by \(V_P = \sqrt{(\lambda + 2\mu)/\rho}\) and \(V_S = \sqrt{\mu/\rho}\).
System (1) is closed by adding physical boundary conditions at the free surface of the medium: $\sigma \vec{n} = 0$, where $\vec{n}$ is the vector normal to the free surface. External forces are neglected.

Since the stress tensor is symmetrical, the unknown vector $\vec{W}$ may be written $\vec{W} = (v_x, v_y, \sigma_{xx}, \sigma_{yy}, \sigma_{xy})^t$ and (1) expresses in matrix form

$$\partial_t \vec{W} - \sum_{\alpha \in \{x,y\}} \vec{A}_\alpha (\rho, \lambda, \mu) \partial_\alpha \vec{W} = 0.$$ \hspace{1cm} [2]

For the spatial discretization of this system, we approximate the physical domain by a polygon $\Omega$, discretized in $N_T$ triangles $T_i$ forming a partition of the domain. Each equation of (2) is multiplied by a scalar test function $\phi_k^{T_i}$ and integrated on each element $T_i$. The characteristics of the medium $(\rho, \lambda, \mu)$ are assumed to be constant over each element $T_i$; to simplify the notation, we denote by $\vec{A}_\alpha^{T_i}$, in what follows, the restriction of the matrix $\vec{A}_\alpha (\rho, \lambda, \mu)$ to $T_i$. Applying Green’s identity, we obtain

$$\int_{T_i} \partial_t \vec{W} \phi_k^{T_i} \, dx \, dy + \sum_{\alpha \in \{x,y\}} \vec{A}_\alpha^{T_i} \int_{T_i} \vec{W} \partial_\alpha \phi_k^{T_i} \, dx \, dy - \vec{A}_\alpha^{T_i} \int_{\partial T_i} \vec{W} \phi_k^{T_i} \, ds = 0,$$ \hspace{1cm} [3]

where $\vec{n}$ is the outward unit normal vector to $T_i$ and $\vec{A}_\alpha^{T_i} = \sum_{\alpha \in \{x,y\}} n_\alpha \vec{A}_\alpha (\rho, \lambda, \mu)$.

As test functions, we choose the standard Lagrange nodal interpolants $\phi_k^{T_i} \in \mathcal{P}_m(T_i)$, set of polynomials of degree $m$ locally defined on the element $T_i$. Each component $W$ of the vector $\vec{W}$ is approximated on $T_i$ by

$$W_{|T_i} (x, y, t) = \sum_{j=1}^{N_m} W_j^{T_i} (t) \phi_j^{T_i} (x, y),$$

where $N_m$ is the number of basis functions and also the number of degrees of freedom on $T_i$. Including this approximation in (3), the first term writes

$$\forall k = 1, \ldots, N_m \int_{T_i} \partial_t \vec{W} \phi_k^{T_i} \, dx \, dy = \sum_{j=1}^{N_m} M_{k,j}^{T_i} \frac{d}{dt} \vec{W}_j^{T_i} \text{ and } \vec{A}_\alpha^{T_i} = \int_{T_i} \phi_j^{T_i} \phi_k^{T_i} \, dx \, dy,$$

where $M_{k,j}^{T_i}$ is the mass matrix in the element $T_i$. Following the same method for the second integral of (3), we obtain

$$\forall k = 1, \ldots, N_m \sum_{\alpha \in \{x,y\}} \vec{A}_\alpha^{T_i} \int_{T_i} \vec{W} \partial_\alpha \phi_k^{T_i} \, dx \, dy = \sum_{\alpha \in \{x,y\}} \vec{A}_\alpha^{T_i} \sum_{j=1}^{N_m} G_{\alpha,k,j}^{T_i} \vec{W}_j^{T_i},$$

where $G_{\alpha,k,j}^{T_i} = \int_{T_i} \phi_j^{T_i} \partial_\alpha \phi_k^{T_i} \, dx \, dy$.

For the last term of (3), the integral on $\partial T_i$, we split the boundary in internal and boundary faces. We define $N(i)$ the set of the indices of the neighboring elements of $T_i$ and $F_{il}$ denotes each internal face common to the elements $T_i$ and $T_l$ (i.e. $F_{il} = T_i \cap T_l$). Finally, $B(i)$ is the set of the indices $l$ of the faces which are common to $T_i$ and the boundary of the domain $\partial \Omega$. Such faces are denoted by $F_{il}^{B(i)} = T_i \cap \partial \Omega$ for $l \in B(i)$. The splitting of the boundary leads to

$$\vec{A}_\alpha^{T_i} \int_{\partial T_i} \vec{W} \phi_k^{T_i} \, ds = \sum_{l \in N(i)} \vec{A}_\alpha^{T_l} \int_{F_{il}} \vec{W} \phi_k^{T_l} \, ds + \sum_{l \in B(i)} \vec{A}_\alpha^{T_l} \int_{F_{il}^{B(i)}} \vec{W} \phi_k^{T_l} \, ds.$$ \hspace{1cm} [4]
For an interior face, the associated boundary integral term is computed via the average value on this face \( \overline{W}_{|F_i} = \left( \overline{W}^{T_i} + \overline{W}^{T_i} \right) / 2 \). For a face \( F^{B_i} \) on the boundary of the domain, the free surface condition \( \overline{n} \overline{f} = 0 \) is introduced weakly in the second term of (4). Finally, we define the vectors \( \overline{W}^{T_i} \) (\( \alpha = x, y \)) and \( \overline{S}^{T_i}_{\alpha \beta} \) (\( \alpha, \beta = x, y \)) which contain respectively the \( N_m \) values of the velocity components \( v_{\alpha} \) and the three stress components \( \sigma_{\alpha \beta} \) in the element \( T_i \). Thus, the spatial discretisation is summarized by

\[
\begin{align*}
M^{T_i} \frac{d}{dt} \tilde{V}_{\alpha}^{T_i} &= F^{T_i}_{\alpha} \left( \tilde{S}^{n+\frac{1}{2}} \right) \quad \alpha = x, y, \\
M^{T_i} \frac{d}{dt} \tilde{S}^{T_i}_{\alpha \beta} &= G^{T_i}_{\alpha \beta} \left( \tilde{V}^{n+1} \right) \quad \alpha, \beta = x, y,
\end{align*}
\]

where \( F_{\alpha} \) and \( G_{\alpha \beta} \) are discrete operators collecting the integrals on \( T_i \) and \( \partial T_i \).

3. TIME DISCRETIZATION

For the time discretization, we apply an explicit leapfrog scheme which results, when combined with the flux (\( \overline{S} \)), in a non-dissipative scheme [4]

\[
\begin{align*}
M^{T_i} \frac{\tilde{V}^{T_i}_{\alpha}}{\Delta t}^{n+1} - \frac{\tilde{V}^{T_i}_{\alpha}}{\Delta t}^{n} &= F^{T_i}_{\alpha} \left( \tilde{S}^{n+\frac{1}{2}} \right) \quad \alpha = x, y, \\
M^{T_i} \frac{\tilde{S}^{T_i}_{\alpha \beta}}{\Delta t}^{n+\frac{1}{2}} - \frac{\tilde{S}^{T_i}_{\alpha \beta}}{\Delta t}^{n+\frac{1}{2}} &= G^{T_i}_{\alpha \beta} \left( \tilde{V}^{n+1} \right) \quad \alpha, \beta = x, y,
\end{align*}
\]

where \( \Delta t \) is the time step of the scheme. Note that the initialisation of the scheme needs the velocities at \( t = t_0 \) and the stresses at \( t = t_0 + \frac{\Delta t}{2} \). As this time discretization scheme is only second order accurate, the global accuracy of the scheme can be penalized when higher-degree polynomials (\( m > 2 \)) are used for spatial approximation [4]. Then, we propose a higher-order leapfrog scheme following the method, proposed for the Maxwell’s equations, by Young [15] or Spachmann et al. [13] and applied to a DG method by Fahs [5]. For a detailed description of the method, we introduce a simplified two equation problem whose unknowns are \( v(x, t) \) and \( \sigma(x, t) \)

\[
\partial_t v = f(\sigma) \quad \text{and} \quad \partial_t \sigma = g(v).
\]

From Taylor developments, we can derive a leapfrog scheme based on velocities at even time steps and stresses at odd time steps. We rather choose to divide the time step by two and we obtain, for the simplified system (7)

\[
\begin{align*}
v^{n+1} &= v^n + \Delta t \partial_t v^{n+\frac{1}{2}} + \frac{\Delta t^3}{24} \partial_{ttt} v^{n+\frac{1}{2}} + O(\Delta t^5), \\
\sigma^{n+\frac{3}{2}} &= \sigma^{n+\frac{1}{2}} + \Delta t \partial_t \sigma^{n+1} + \frac{\Delta t^3}{24} \partial_{ttt} \sigma^{n+1} + O(\Delta t^5).
\end{align*}
\]

Firstly, the terms \( \partial_t v^{n+\frac{1}{2}} \) and \( \partial_t \sigma^{n+1} \) are evaluated using (7) at times \( (n + \frac{1}{2}) \Delta t \) for \( v \) and \( (n + 1) \Delta t \) for \( \sigma \). Considering only these derivatives in (8) and neglecting the higher-order terms leads to the classical second-order leapfrog scheme

\[
v^{n+1} = v^n + \Delta t \, v^{n+\frac{1}{2}} \quad \text{and} \quad \sigma^{n+\frac{3}{2}} = \sigma^{n+\frac{1}{2}} + \Delta t \, \sigma^{n+1},
\]

with \( v^{n+\frac{1}{2}} = f(\sigma^{n+\frac{1}{2}}) \) and \( \sigma^{n+1} = g(v^{n+1}) \). When applied to the discrete system (5), it is equivalent to the standard leap-frog scheme (6).
The construction of a higher order leapfrog scheme needs values for $\partial_{ttt}v^{n+\frac{1}{2}}$ and $\partial_{ttt}\sigma^{n+1}$, obtained, as previously, by successive derivatives of (7). We then obtain a fourth-order leapfrog scheme

$$v^{n+1} = v^n + \Delta t v_*^{n+\frac{1}{2}} + \frac{\Delta t^3}{24} v_{**}^{n+\frac{1}{2}}$$

and

$$\sigma^{n+\frac{1}{2}} = \sigma^n + \Delta t \sigma_*^{n+\frac{1}{2}} + \frac{\Delta t^3}{24} \sigma_{**}^{n+\frac{1}{2}}, \quad \text{[9]}$$

with

$$\sigma_{**}^{n+\frac{1}{2}} = g \left( v_{**}^{n+\frac{1}{2}} \right),$$

and

$$v_{**}^{n+1} = f \left( \sigma_{**}^{n+1} \right),$$

$$\sigma_{**}^{n+1} = g \left( v_{**}^{n+1} \right).$$

This method is applied to (2) using the spatial discretization (5) and a fourth-order leapfrog scheme writes

$$\begin{aligned}
\left\{ \begin{array}{l}
\left( \vec{V}_{a}^{T_{\alpha}} \right)^{n+1} = \left( \vec{V}_{a}^{T_{\alpha}} \right)^n + \Delta t \left( \vec{V}_{a}^{T_{\alpha}} \right)_{**}^{n+1} + \frac{\Delta t^3}{24} \left( \vec{V}_{a}^{T_{\alpha}} \right)^{n+\frac{3}{2}} \quad \alpha = x, y,
\left( \vec{S}_{\alpha \beta}^{T_{\alpha}} \right)^{n+\frac{1}{2}} = \left( \vec{S}_{\alpha \beta}^{T_{\alpha}} \right)^n + \Delta t \left( \vec{S}_{\alpha \beta}^{T_{\alpha}} \right)_{**}^{n+1} + \frac{\Delta t^3}{24} \left( \vec{S}_{\alpha \beta}^{T_{\alpha}} \right)^{n+\frac{3}{2}} \quad \alpha, \beta = x, y,
\end{array} \right. \text{[10]}
\end{aligned}$$

with

$$\begin{aligned}
\left\{ \begin{array}{l}
\left( \vec{V}_{a}^{T_{\alpha}} \right)^{n+\frac{1}{2}} = \left( \mathcal{M}_{T_{\alpha}}^{-1} F_{a} \right) \left( \vec{S}_{\alpha}^{T_{\alpha}} \right)^{n+\frac{1}{2}},
\left( \vec{S}_{\alpha \beta}^{T_{\alpha}} \right)^{n+\frac{1}{2}} = \left( \mathcal{M}_{T_{\alpha}}^{-1} G_{a \beta} \right) \left( \vec{V}_{a}^{T_{\alpha}} \right)^{n+\frac{1}{2}},
\left( \vec{V}_{a}^{T_{\alpha}} \right)^{n+1} = \left( \mathcal{M}_{T_{\alpha}}^{-1} F_{a} \right) \left( \vec{S}_{\alpha}^{T_{\alpha}} \right)^{n+1},
\left( \vec{S}_{\alpha \beta}^{T_{\alpha}} \right)^{n+1} = \left( \mathcal{M}_{T_{\alpha}}^{-1} G_{a \beta} \right) \left( \vec{V}_{a}^{T_{\alpha}} \right)^{n+1}.
\end{array} \right. \end{aligned}$$

In practice, for a given approximation in space, the fourth-order leapfrog scheme needs three times the number of arithmetic operations (to calculate the fluxes $F$ and $G$) than the classical leapfrog scheme and twice as much memory storage since additional arrays have to be defined for $\left( \vec{V}_{a}^{T_{\alpha}} \right)^{n+\frac{1}{2}}$ and $\left( \vec{S}_{\alpha \beta}^{T_{\alpha}} \right)^{n+1}$. Following the same procedure, higher order (sixth, eighth and more) leapfrog schemes could be derived.

### 4. Numerical Results

We realize some numerical studies of the properties of the method. A mathematical analysis of the stability and convergence of this new scheme is underway and will be the subject of a further publication. The method has been first applied to the propagation of an eigenmode. The computational domain $\mathcal{D}$ is the unit square and free surface boundary conditions are applied on all boundaries. We consider the $(1,1)$ mode whose exact solution is [6]

$$\begin{aligned}
\begin{array}{l}
v_x = a \cos \pi x \sin \pi y \cos at \\
v_y = -a \sin \pi x \cos \pi y \cos at \\
v = \sigma_{xx} = -b \sin \pi x \sin \pi y \sin at \\
v = \sigma_{yy} = b \sin \pi x \sin \pi y \sin at \\
v = \sigma_{xy} = 0
\end{array}
\end{aligned} \quad \text{[11]}$$

where $a = \sqrt{2} \pi V_s$ and $b = 2 \pi \mu$. The medium properties are $\rho = 1, \lambda = 0.5$ and $\mu = 0.25$ leading to $V_\rho = 1$ and $V_S = 0.5$. The initialisation of the leapfrog scheme is done from the exact solution (11) at $t = 0$ for $v$ and $t = \frac{\Delta t}{2}$ for $\sigma$, $\Delta t$ being the time step of the scheme. The notation $P_k$-$L_F$ ($k=1,\ldots, 4$ and $l=2$ or $4$) refers to a spatial discretization based on a polynomial basis of degree $k$ and a classical second-order leapfrog time scheme (LF2) or its extension (LF4).
First, in order to check numerically the stability of the different methods, we solve this problem for different values of the time step. This time step depends on geometrical properties of the mesh and is proportional to a CFL value which is a data of the simulation by
\[ \Delta t = \min_{T_i} \left[ CFL \times h_i / (V_p)_i \right] , \]
a formula deduced from the optimal stability condition for finite volumes applied to the reference triangle (as in [4]) and where the mesh spacing \( h_i \) is the smallest edge of the triangle \( T_i \). We have performed such studies for all \( Pk-LFi \) combinations and the maximum values of the CFL numbers ensuring stability are given in the table 1. The value of the CFL number depends on both time and space schemes: its value decreases when the spatial discretization order increases and time steps of the LF4 schemes are greater than those of the LF2 schemes. For any space scheme, we have \( CFL_{LF4} \approx 2.5 \times CFL_{LF2} \).

**Table 1. Maximum CFL number for different methods**

For the convergence study of these schemes, we solve the problem using a series of meshes of different mesh spacing \( h \). Uniform meshes are obtained by splitting quadrangular cells into two triangles and unstructured meshes are constructed via a mesher from an uniform distribution of the nodes on the boundaries of the domain. The mesh spacing \( h \) is the smallest edge in the mesh. All results correspond to solutions at time \( t = 5.0 \) s. We display, in figure 1, the \( L^2 \)-error between computed and exact solutions as a function of \( h \) for different schemes applied to regular (left figure) and irregular meshes (right figure) and using the classical leapfrog scheme (LF2, first line of figures). The convergence is second order for both types of meshes, even if the error level is lower for the highest order schemes. The use of higher degree basis function do not improve the convergence of the scheme. The results for unstructured meshes are slightly better than those for uniform meshes. This is probably due to the choice of Delaunay meshes which have well known properties [4].

We present, in Figure 1, the same results for the fourth-order leapfrog extension (LF4, second line of figures), for uniform (left figure) and unstructured meshes (right figure). Convergence is clearly improved when high-order time schemes are used, for both types of meshes. In particular, for \( P3-LF4 \) and \( P4-LF4 \) methods, a fourth-order convergence is obtained. This proves that the use of fourth-degree basis functions (P4) is optimal when combined to a fourth-order time scheme (LF4). In summary, the values of the convergence orders of the different methods, are collected in Table 2 and confirm the results of the figures.

**Table 2. Values of convergence orders of different methods**

Finally, we examine the efficiency of the different methods by plotting, in Figure 2, for uniform meshes, the evolution of the \( L^2 \)-error at time \( t = 5.0 \) s as a function of the CPU time of the simulation. For a given level of accuracy, the two most accurate methods (\( P3-LF4 \) and \( P4-LF4 \)) are also the most efficient since the given error level is obtained for lower CPU times. The ratio between the minimum and the maximum CPU times to reach the given level of accuracy, corresponding respectively to the \( P4-LF4 \) and \( P2-LF2 \) schemes is about 100. The LF4 scheme needs more operations but higher-order schemes
are more efficient as coarser meshes can be used to reach a desired accuracy level. The use of greater times steps in the LF4 scheme case compensates for the extra cost due to the multi-step procedure.

5. CONCLUSION

We proposed a fourth-order leapfrog time scheme combined with a high-order discontinuous Galerkin method for the solution of the elastodynamic equations. Following the previous results obtained in [4], when global high-order accuracy is sought, it is worth

Figure 1. Convergence study. $L^2$-error as a function of the mesh spacing $h$ for Pk-LF2 schemes ($k=2,3,4$) (first line) and Pk-LF4 schemes (second line) using uniform (left) and unstructured meshes (right).

Figure 2. Efficiency of the methods. $L^2$-error at time $t = 5.0$ s as a function of CPU time for Pk-LFi schemes ($k=2,3,4$, $i=2$ or $4$) (uniform meshes).
while to use higher-order space interpolation while keeping the classical leap-frog time scheme since accuracy is not improved while CPU costs are increased. This extension of the leapfrog scheme to fourth-order (or to any even order) modifies the classical leapfrog scheme in a multi-step procedure but where the additional cost is compensated by the use of greater time steps. This method has been applied to the propagation of an eigenmode which permits numerical studies of stability, convergence, accuracy and efficiency of the scheme. Note that fourth-order convergence is attained with the P4-LF4 version when it is limited to second order when the classical leapfrog scheme is used.
